

SESSION 12. FINDING GENES

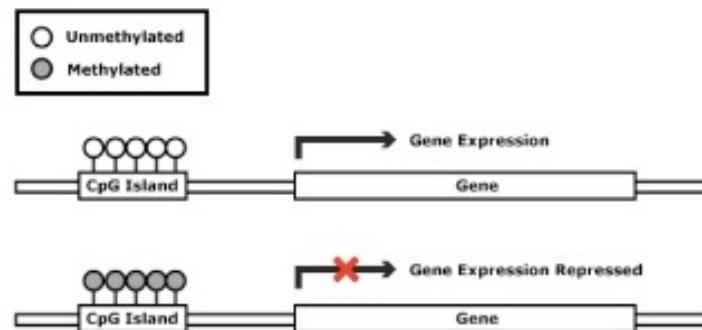

Going ashore at CpG islands

Chemistry on the CpG island - how the methyl group is removed from lysine by KDM

CpG islands on genome ocean

- Human genome projects were completed back in 2003.
- What are the genetic information represented in the three billion bases ?
- Regions that give rise to RNAs that in turn encode proteins Protein-coding genes (1.5~ 2.0% for human) and non-coding genes. E.coli contains as much as 83% of coding sequence.
- Analogy to finding a needle in a haystack → require a highly specific method
- CpG island well defines the transcription start site (TSS)

Eukaryotic transcription regulation

- Transcription of genes takes place with the help of the RNA polymerases
 - ▣ RNA pol I, II, and III
 - ▣ RNA pol II is responsible for the transcription of PCGs, snRNA, microRNA, and lncRNA genes.
 - ▣ RNA pol I is responsible for the transcription of rRNAs
 - ▣ RNA pol III is responsible for the transcription of tRNA, 5s rRNA,... other ncRNAs

Table 21-1 Properties of Eukaryotic RNA Polymerases

RNA Polymerase	Location	Main Products	α -Amanitin Sensitivity
I	Nucleolus	Precursor for 28S rRNA, 18S rRNA, and 5.8S rRNA	Resistant
II	Nucleoplasm	Pre-mRNA and most snRNA	Very sensitive
III	Nucleoplasm	Pre-tRNA, 5S rRNA, and other small RNAs	Moderately sensitive*
Mitochondrial	Mitochondrion	Mitochondrial RNA	Resistant
Chloroplast	Chloroplast	Chloroplast RNA	Resistant

*In mammals.

- Transcription factors are also required for initiation of RNA pol II.
 - ▣ General TF - for initiation of transcription of all protein genes
 - ▣ Specific TF - for regulation of subset of genes through enhancer or repressor

Cis-regulatory element of transcription

- Specific TF binding site (enhancer or repressor)
 - ▣ Ex, Oestrogen receptor recognizes a sequence “AGGTCANNNTGACCT”
 - ▣ Motif (k-mer) enrichment analysis in a specific set of genes
 - ▣ ChIP-seq (chromatin IP followed by sequencing)

- General TF binding site (core + proximal promoter) *for identifying TSS*
 - ▣ TATA box: 10~25% of all human genes have this TATA box, recognized by TFIID

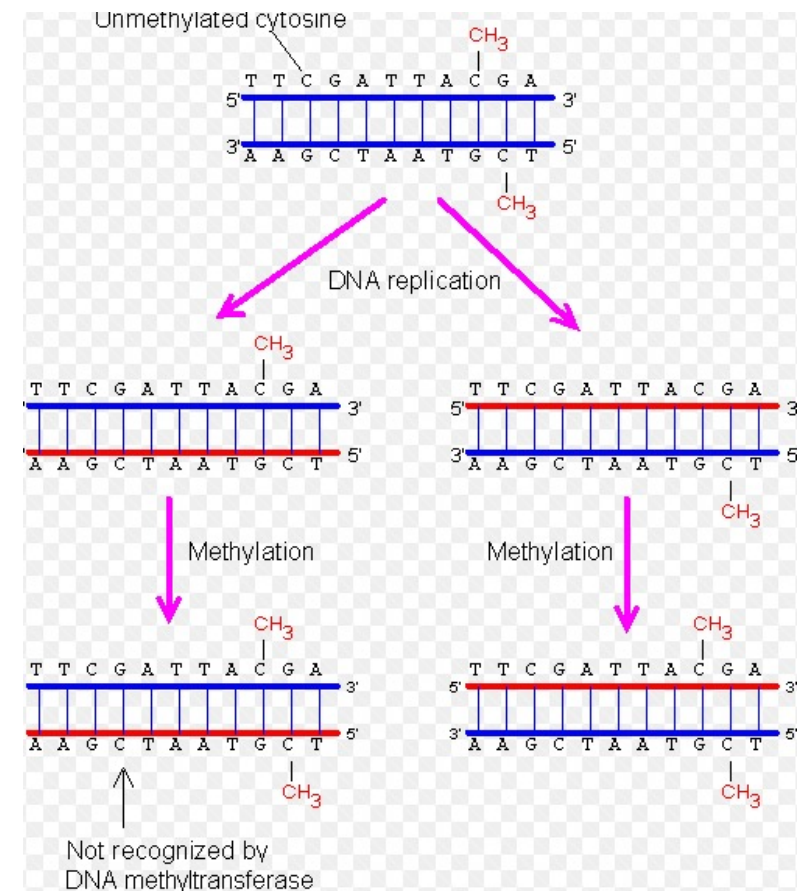

CpG islands

- A more common feature of transcription initiation regions are CpG islands
- The regions close to the TSS of ~60-70% of all human genes.
- CpG → C + phosphodiester bond + G (dinucleotide)
- CpG islands where the frequency of CpG sites is much higher than the background frequency of this dinucleotide
- C: 0.19 G:0.19 → CpG: 0.026 (observed) / 0.19X0.19=0.036 (expected)

CpG islands

- CpG → methylation on C → TpG mutation over evolution → depletion of CpG
- CpG near TSS → low methylation on C → high freq. of CpG
- The majority (70%) of CpG dinucleotides in a mammalian genome are methylated but the CpG near TSSs are typically not methylated.
- **Epigenetic inheritance:** the methylation pattern in a specific cell may be transmitted to the progeny cells.
- DNA methylation is also an important basis for genomic imprinting of either maternal or paternal origin.

Finding CpG islands

- Original definition of CpG islands (Gardiner-Garden and Frommer, 1987)
 - A region **at least 200 bp in length** with a GC content of **at least 50%** and an **observed CpG/expected CpG ratio greater than 0.6**.
 - Drawback with this definition → many Alu repeats of the human genome will be incorrectly predicted as CpG (~ a million copy of Alu elements)

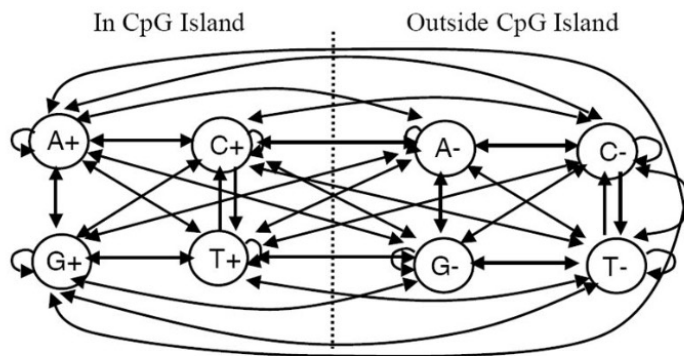

- Alternative definition of CpG islands (Takai and Jones 2002) 
 - Important criterion for optimizing specificity in methods of CpG island
 - The total length of CpG island should be at least 500 nt
 - The G+C content should be at least 55%
 - The ratio b/w the frequency of observed CpG sites and the frequency of expected CpG sites should be at least 0.65.
 - $$\frac{f_{CpG}}{f_C f_G} = \frac{SN_{CpG}}{N_C N_G}$$

- Alternative prediction using HMM (Durbin 2007)

Finding CpG islands

- Alternative prediction using HMM (Durbin 2007)

An HMM for CpG islands

Emission probabilities are 0 or 1. E.g. $e_{G-}(G) = 1$, $e_{G-}(T) = 0$

See Durbin et al., *Biological Sequence Analysis*, Cambridge 1998

Optimal path that maximizes the emission * the transition prob.

Viterbi Algorithm: An Example

cpy.py

```
#!/usr/bin/python

import re, sys
filename = sys.argv[1]
win = 500
step = 10
seq = ''
for line in open(filename): # a shorter sequence
    if not re.search('>', line):
        line = line.rstrip()
        seq = seq + line
print 'pos\tcpg\tcg_ratio\tcg_obs_exp'
for i in range(0, len(seq) - win, step):
    testseq = seq[i:i + win]
    c = float(testseq.count('C'))
    g = float(testseq.count('G'))
    cg = float(testseq.count('CG'))
    cg_ratio = (c + g) * 100 / len(testseq)
    cg_obs_exp = cg * len(testseq) / (c * g)
    pos = i + win / 2
    if cg_ratio >= 55 and cg_obs_exp >= 0.65:
        print pos, '\t', 1, '\t', cg_ratio, '\t', cg_obs_exp
    else:
        print pos, '\t', 0, '\t', cg_ratio, '\t', cg_obs_exp
```

```
[jwnam@biglab-master Session11]$ python cpg.py short.fa
pos      cpg      cg_ratio  cg_obs_exp
250      0        36.2      0.133547008547
